

Network Flow Applications cont'd 11.06

See Jeff Erickson's text "Algorithms", Chap 11.

11.1 Edge Disjoint Paths

What is the max number of **edge disjoint** paths from s to t in directed graph G .

How to compute it using Network Flow algs:

- give every edge capacity = 1.
- Run Network Flow alg
- the value of the flow is exactly the number of edge-disjoint s - t paths.

Using Orlin's alg, this can be done in $O(nm)$

But Ford & Fulkerson (generally $O(nm^2)$) also runs \uparrow nm iterations, $O(n)$ /iteration

In $O(nm)$ in this case since

- value of flow increases by ≥ 1 each iteration.
- total value is $\leq n-1$

Reduce max # edge-disjoint paths in undirected G
to max # edge-disjoint path in directed G :

Vertices can have capacities.

In addition to the other constraints, each vertex v has a capacity $c(v)$ for flow that can go through v on the way from s to t .

$$\sum_{u \rightarrow v} f(u \rightarrow v) \leq c(v)$$

Reduce Network-Flow with vertex-capacities to
Network Flow (Classic) \circ

The reduction takes $\Theta(m)$ time (in a connected graph, $m \geq n-1$)

\circ Running time for NF w/ vertex-capac is $\Theta(nm)$
(using orlin's alg)

11.4 Tuple Selection.

- Bipartite max matching is a special case of this
- Lets start with an example:

Exam Scheduling

VIU has classes that need exams to be held in rooms and that will be overseen by proctors.

Constraints and Inputs

$E[1 \dots n]$ where $E[i] = \#$ of students in class i

$S[1 \dots r]$ where $S[j] = \#$ of seats in room j

A class i can have its exam in room j only if

$$E[i] \leq S[j]$$

$A[1 \dots t, 1 \dots p]$ where $A[k, \ell] = \text{TRUE}$

iff k^{th} proctor is available during k^{th} time slot

Furthermore, no proctor supervises > 5 exams.

Total size of input is $N = n + r + tp$

Goal: Schedule classes, rooms, time slots, proctors

so as to meet the constraints.

(or say no such schedule is possible)

To solve :

NF \Rightarrow Schedule

Suppose \exists a NF in the network of value _____

1. It assigns each proctor to ≤ 5 time slots, ≤ 1 class per time slot
 2. It obeys proctor \leftrightarrow time slot constraints.
 3. It identifies, for each class, exactly 1 (room, time slot, proctor) triple
 4. No room has ≥ 2 classes in same time slot
- o Follow the flow of 1 unit from a class - it will identify the room + time slot and proctor.

Schedule \Rightarrow NF

Suppose \exists a schedule that meets all constraints.

For each (class, room, time slot, professor) tuple, push 1 unit of flow through that path in the NF diagram. It will meet all the flow-capacity constraints (because we built the NF instance to reflect those constraints!)

- through each class will be a flow of 1

- \therefore total flow will be n .
