# An Inheritance Hierarchy

## Account

acctNum()  
acctOwner()  
acctBalance()  
deposit()  
withdraw()

## SavingsAccount

acctNum()  
acctOwner()  
acctBalance()  
deposit()  
withdraw()

interestRate()

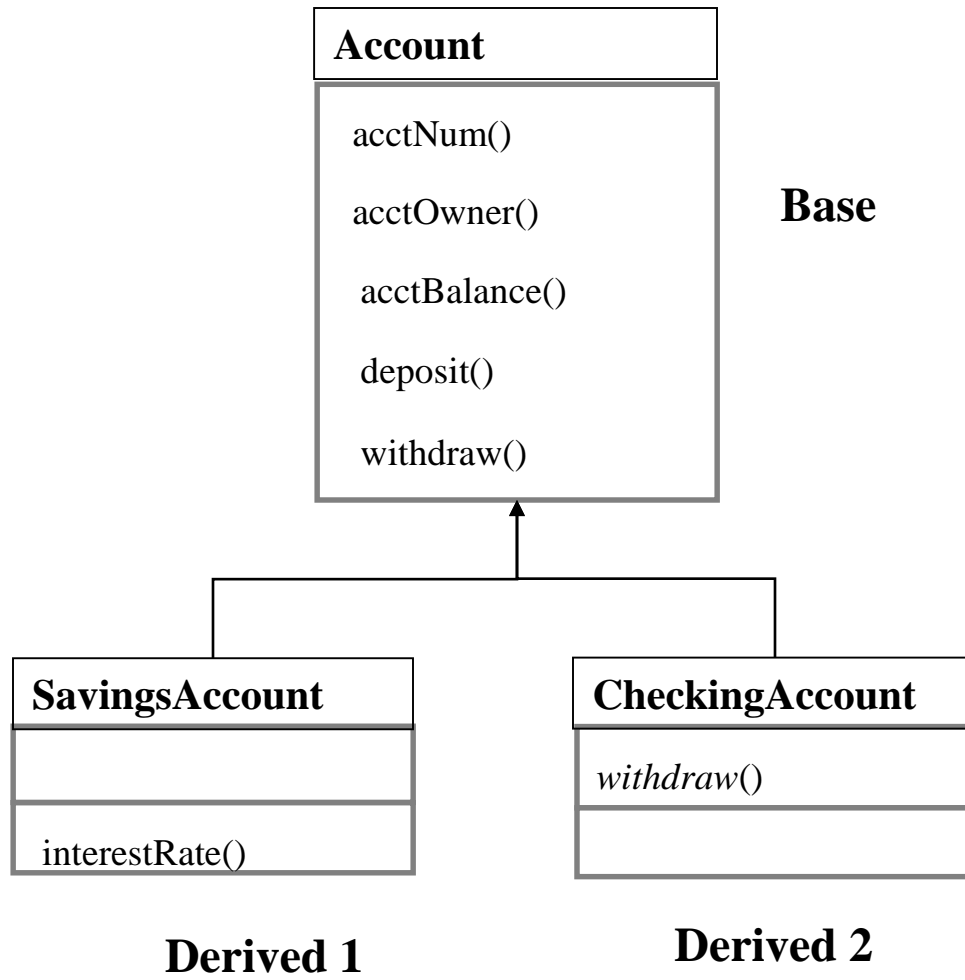

## CheckingAccount

acctNum()  
acctOwner()  
acctBalance()  
deposit()  
*withdraw()*

# Inheritance

- Classes may be arranged in a class hierarchy where one class (**base class**) is a generalisation of one or more other classes (**derived classes**).
- A derived class **inherits** the **attributes** and **behaviours** from its base class and **may add new operations** or **attributes** of its own.
- Generalisation is implemented as inheritance in OOP languages.

# An Inheritance Hierarchy

# Advantages of Inheritance

- It is a **reuse mechanism** at both the design and the programming level
- It is an **abstraction mechanism** which may be used to classify entities

# Base class and Derived class

- The advantage of making a new class a derived class is that it will *inherit* attributes and operations of its base class.
- Derived classes extend existing classes in three ways:
  - By defining new (additional) attributes and operations.
  - By overriding (changing the behavior) existing operations.
  - By hiding existing attributes and operations.

# Derived classes

- Derived classes are used to define special cases, extensions, or other variations from the originally defined class.

Example: *SavingsAccount* and *CheckingAccount* can be derived from the *Account* class

```
class Account {  
    private:  
        string number;  
        string owner;  
        double balance;  
    public:  
        string acctNum() {...}  
        string acctOwner() {...}  
        double balance() {...}  
        void deposit(double) {...}  
        void withdraw(double) {...}  
};
```

```
class SavingsAccount : public Account {  
    private:  
        double intRate;  
    public:  
        void interestRate(double) {...}  
};
```

```
class CheckingAccount: public Account {  
    public:  
        void withdraw(double) {...}  
};
```

# Derived classes

## Account

```
acctNum()  
acctOwner()  
balance()  
deposit()  
withdraw()
```

## SavingsAccount

```
acctNum()  
acctOwner()  
balance()  
deposit()  
withdraw()  
  
interestRate()
```

## CheckingAccount

```
acctNum()  
acctOwner()  
balance()  
deposit()  
withdraw()  
  
withdraw()
```

- No new code has to be written for *acctNum()*, *acctOwner()*, *balance()*, and *deposit()* operations, they are **inherited** from the **base class** into the **derived classes**.
- *SavingsAccount* inherited *withdraw()* operation and added a new *rate()* operation.
- *CheckingAccount* has different rules to follow for withdraw, i.e, overrode *withdraw()* operation.

# Inheritance: Rules

- Derived class **inherits** but **cannot access private member variables**
- Derived class does not inherit **private member functions**.
- Derived class **inherits** every **non-private member variables** and **non-private member functions** **except**:
  - **Constructors** (default, regular, copy, and move)
  - **Destructor**
  - **Assignment operators** (copy assignment and move assignment)
- Derived class **does not inherit friend functions**
